

Meropenem vs untreated: volcano plot

Significance (t-test) ● Down (Meropenem-depleted) ● Not significant

Strain AB042, Stationary phase. Panel C: volcano plot, log₂(Meropenem/untreated) per 1kb window (x) vs -log₁₀(t-test p-value) (y); n = 4004 windows (0 excluded for zero coverage in at least one condition); 0 significantly up, 6 significantly down ($|\log_2\text{FC}| > 1$ and t-test p < 0.05). Vertical lines mark log₂FC = -1/+1; horizontal line marks p = 0.05. Caution: p-values are per-window from only 2 replicates per condition (t-test df = 2); BH-adjusted p-values are in the results CSV. Mann-Whitney U p-values (also in the CSV) are of limited value at this replicate count: the exact test's minimum attainable two-sided p-value is 1/3 with no ties among the four values, but read counts are discrete and frequently tied, which makes R fall back to a normal approximation that can occasionally read below that nominal floor. Either way it is under-powered here and is not used to drive the y-axis (0 of 4004 windows show raw Mann-Whitney U p < 0.05, for reference).
