

## Meropenem vs untreated: volcano plot

Significance (t-test) • Not significant

Strain LAC-4, Exponential phase. Panel C: volcano plot,  $\log_2(\text{Meropenem}/\text{untreated})$  per 1kb window (x) vs  $-\log_{10}(\text{t-test p-value})$  (y);  $n = 3954$  windows (0 excluded for zero coverage in at least one condition); 0 significantly up, 0 significantly down ( $|\log_2\text{FC}| > 1$  and t-test  $p < 0.05$ ). Vertical lines mark  $\log_2\text{FC} = -1/+1$ ; horizontal line marks  $p = 0.05$ . Caution: p-values are per-window from only 2 replicates per condition (t-test  $\text{df} = 2$ ); BH-adjusted p-values are in the results CSV. Mann-Whitney U p-values (also in the CSV) are of limited value at this replicate count: the exact test's minimum attainable two-sided p-value is  $1/3$  with no ties among the four values, but read counts are discrete and frequently tied, which makes R fall back to a normal approximation that can occasionally read below that nominal floor. Either way it is under-powered here and is not used to drive the y-axis (0 of 3954 windows show raw Mann-Whitney U  $p < 0.05$ , for reference).
