

Candidate Inversion Breakpoints: AB030 Hybrid Assembly vs. Reference

Inversion 1: ref 430,141-430,216 bp

Inversion 2: ref 430,218-430,604 bp

Strain AB030. Both NucDiff-called inversions sit on the same 106,967bp assembly contig (contig 5 of 175), not the 1,515,311bp main chromosome scaffold -- this assembly's largest contig is only 29.0% of total assembly length (see Panel C completeness figure), i.e. it is fragmented. Local alignment identity at these breakpoints (97.4% and 97.9%) is below the genome-wide mean for this comparison (99.76%). The two inversion blocks map to opposite ends of the same 107kb contig (positions ~2 and ~106,900) onto two reference windows only ~460bp apart -- a pattern consistent with a contig-end/assembly-junction artifact rather than a confirmed internal biological inversion. CAUTION: treat as a candidate finding pending confirmation via raw long-read breakpoint support (read alignment spanning the junction), not as a confirmed rearrangement.
